Spilite, fine-grained or dense, extrusive igneous (volcanic) rock that is usually free of visible crystals and is commonly greenish or grayish green in colour. Spilites are of basaltic character but contain the feldspar albite in place of the normal labradorite. The dark mineral is a pale-

brown augite; spilites are, however, usually decomposed, and augite is represented by chlorite and calcite.

### *Spilite / rock / Britannica*

Spilite is formed when basaltic lava reacts with seawater, or from hydrothermal alteration when seawater circulates through hot volcanic rocks.

[2] It is a metasomatic rock with a microscopic or very-fine grain size produced by hydrothermal alteration of basalt, and composed of albite or oligoclase , together with chlorite , epidote , calcite , and actinolite . [3]

### *Spilite - Wikipedia*

Since both a volcanic and a hypabyssic milieu is exposed here, these rocks provide abundant material for studying the spilite dilemma.

Consequently, spilites have twice been

Summary. Although the structures and textures of spilites and keratophyres are comparable to those of fresh lavas, recent work has established that they did not acquire their present mineralogy at the time of extrusion. Furthermore, the compositions of many analyzed samples of spilites and keratophyres are shown to lie outside a 'spectrum' of compositions of all comparable fresh igneous rocks.
